

Microservices and Agile Delivery Guide

1. Agile Sprint Cadence

Teams operate in two-week sprints. Each sprint begins with planning, includes daily standups, and ends with a retrospective. Sprint goals must be demo-ready by the review meeting.

2. Microservices vs Monolith

Microservices decompose applications into independently deployable services with bounded contexts. Monolithic architectures keep all modules in one deployable unit. Microservices improve scalability but add network complexity.

3. Continuous Integration

Every pull request triggers automated unit tests, lint checks, and security scans. Builds must pass before merge to the main branch.

4. Service Communication

Services communicate via REST APIs or asynchronous message queues. Synchronous calls require circuit breakers and timeout policies.
